Benchmarking Optimization Software with COPS*

Elizabeth D. Dolan[†] and Jorge J. Moré[‡]

Abstract

We describe version 2.0 of the COPS set of nonlinearly constrained optimization problems. We have added new problems, as well as streamlined and improved most of the problems. We also provide a comparison of the LANCELOT, LOQO, MINOS, and SNOPT solvers on these problems.

Introduction

The COPS [5] test set provides a modest selection of difficult nonlinearly constrained optimization problems from applications in optimal design, fluid dynamics, parameter estimation, and optimal control. In this report we describe version 2.0 of the COPS problems. The formulation and discretization of the original problems have been streamlined and improved. We have also added new problems.

The presentation of COPS follows the original report, but the description of the problems has been streamlined. For each problem we discuss the formulation of the problem and the structural data in Table 0.1 on the formulation. The aim of presenting this data is to provide an approximate idea of the size and sparsity of the problem.

Table 0.1: Description of test problems

Variables
Constraints
Bounds
Linear equality constraints
Linear inequality constraints
Nonlinear equality constraints
Nonlinear inequality constraints
Nonzeros in $\nabla^2 f(x)$
Nonzeros in $c'(x)$

We also include the results of computational experiments with the LANCELOT, LOQO, MINOS, and SNOPT solvers. These computational experiments differ from the original [5] results in that we have deleted problems that were considered to be too easy. Moreover, in the current version of the computational experiments, each problem is tested with four variations.

[‡]Mathematics and Computer Science Division, Argonne National Laboratory, Argonne, Illinois 60439 (more@mcs.anl.gov).

An important difference between this report and the original [5] report is that the tables that present the computational experiments are generated automatically from the testing script. This is explained in more detail below.

Testing Methods

We have performed our trials on sixty-eight variants of seventeen different applications, which constitute version 2.0 of the COPS set. The implementations are written in the AMPL modeling language for use with the AMPL (version 20000906) interfaces to nonlinearly constrained optimization solvers of interest to us. The solvers include LANCELOT (AMPL driver 19990513), LOQO 5.03 (20000528), MINOS 5.5 (19981015), and SNOPT 5.3-4 (19981124).

We have devised a script for running a problem on each solver successively, so as to minimize the effect of fluctuation in the machine load. The script tracks the wall-clock time from the start of the solve, killing any process that runs for more than 3,600 seconds, which we declare unsuccessful. We cycle through all problem variants, recording the wall-clock time as well as the combination of AMPL system time (to interpret the model and compute varying amounts of derivative information required by each solver) and solver time. We consider the times returned by AMPL definitive, but we initially record the wall-clock times to check for discrepancies in the solvers' methods of calculating execution time. We include no problem results for which the AMPL time and the wall-clock time differ by more than ten percent. To further ensure consistency, we have verified that the AMPL time results we present could be reproduced to within ten percent accuracy. All computations were done on a SparcULTRA2 running Solaris 7.

Once all the runs have completed, a parser searches the output files for key text patterns indicating whether the solver completed successfully. The script then gathers the data we need into tables and other files for later calculations.

The AMPL interfaces to these solvers provide numerous options. We set options for each solver and execute our final complete runs with the same options for all problems. The options involve setting the output level so that we can gather the data we want, increasing the iteration limits as much as allowed, and increasing the super-basics limits for MINOS and SNOPT to 5000. None of the failures we record in the final trials include any solver error messages about having violated these limits.

We realize that testing optimization software is a notoriously difficult problem and that there may be objections to the testing presented in this report. For example, performance of a particular solver may improve significantly if non-default options are given. Another objection is that we only use one starting point per problem and that the performance of a solver may be sensitive to the choice of starting point. We also have used the default stopping criteria of the solvers. This choice may bias results but should not affect comparisons that rely on large time differences. A final objection is that not all solvers use the same derivative information; MINOS and SNOPT use first-order information, while LANCELOT and LOQO use second-order information. In spite of these objections, we feel that it is essential that we provide some indication of the performance of optimization solvers on interesting problems. This report is an effort in this direction.

1 Largest Small Polygon

Find the polygon of maximal area, among polygons with n_v sides and diameter $d \leq 1$.

Formulation

This is a classic problem (see, for example, Graham [16]). If (r_i, θ_i) are the coordinates of the vertices of the polygon, then we must maximize

$$f(r, \theta) = \frac{1}{2} \sum_{i=1}^{n_v-1} r_{i+1} r_i \sin(\theta_{i+1} - \theta_i)$$

subject to the constraints

$$\begin{aligned} r_i^2 + r_j^2 - 2r_i r_j \cos(\theta_i - \theta_j) &\leq 1, & 1 \leq i \leq n_v, & \quad i < j \leq n_v, \\ \theta_i &\leq \theta_{i+1}, & 1 \leq i < n_v, & \\ \theta_i \in [0, \pi], r_i &\geq 0, & 1 \leq i \leq n_v. & \end{aligned}$$

Our implementation follows [14] and fixes the last vertex by setting $r_{n_v} = 0$ and $\theta_{n_v} = \pi$. By fixing a vertex at the origin, we can add the bounds $r_i \leq 1$.

Graham [16] showed that the optimal solution is regular for odd n but not regular for even n except $n = 4$. Another interesting feature of this problem is the presence of order n_v^2 nonlinear nonconvex inequality constraints. We also note that as $n_v \rightarrow \infty$, we expect the maximal area to converge to the area of a unit-diameter circle, $\pi/4 \approx 0.7854$. This problem has many local minima. For example, for $n_v = 4$ a square with sides of length $1/\sqrt{2}$ and an equilateral triangle with another vertex added at distance 1 away from a fixed vertex are both global solutions with optimal value $f = \frac{1}{2}$. Indeed, the number of local minima is at least $O(n_v!)$. Thus, general solvers are usually expected to find only local solutions. Data for this problem appears in Table 1.1.

Table 1.1: Largest-small polygon problem data

2 Distribution of Electrons on a Sphere

Given n_p electrons, find the equilibrium state distribution (of minimal Coulomb potential) of the electrons positioned on a conducting sphere.

Formulation

This problem, known as the Thomson problem of finding the lowest energy configuration of n_p point charges on a conducting sphere, originated with Thomson's plum pudding model of the atomic nucleus. This problem is representative of an important class of problems in physics and chemistry that determine a structure with respect to atomic positions.

The potential energy for n_p points (x_i, y_i, z_i) is defined by

$$f(x, y, z) = \sum_{i=1}^{n_p-1} \sum_{j=i+1}^{n_p} ((x_i - x_j)^2 + (y_i - y_j)^2 + (z_i - z_j)^2)^{-\frac{1}{2}},$$

and the constraints on the n_p points are

$$x_i^2 + y_i^2 + z_i^2 = 1, \quad i = 1, \dots, n_p.$$

Data for this problem appears in Table 2.1.

This problem has many local minima at which the objective value is relatively close to the objective value at the global minimum. Experimental and theoretical results [18, 20] show that

$$\min \{f(v_1, \dots, v_{n_p}) : \|v_i\| = 1, 1 \leq i \leq n_p\} \geq \frac{1}{2}n_p^2(1 - \varepsilon), \quad 0 \leq \varepsilon \leq \left(\frac{1}{n_p}\right)^{1/2}.$$

Also, the number of local minima grows exponentially with n_p . Thus, determining the global minimum is computationally difficult, and solvers are usually expected to find only a local minimum.

MINOS cannot solve the problem for $n_p > 50$. For $n_p = 200$ it gives the error message *unbounded (or badly scaled) problem*.

Figure 2.1: Optimal distribution of electrons on a sphere, $n_p = 100$

3 Hanging Chain

Find the chain (of uniform density) of length L suspended between two points with minimal potential energy.

Implementation

This classical problem (see Cesari [11, pages126-127]) was suggested by Hans Mittelmann. In this problem we need to determine a function $x(t)$, the shape of the chain, that minimizes the potential energy

$$\int_0^1 x \sqrt{1 + x'^2} dt$$

subject to the constraint on the length of the chain,

$$\int_0^1 \sqrt{1 + x'^2} dt = L,$$

and the end conditions $x(0) = a$ and $x(1) = b$. We reformulate this problem as a control problem in terms of the function $u = x'$. The optimal control version of the problem is

$$\int_0^1 x \sqrt{1 + u^2} dt$$

subject to a differential equation and a constraint on the length of the chain,

$$x' = u, \quad \int_0^1 \sqrt{1 + u^2} dt = L.$$

We discretize the integrals and the differential equation with the trapezoidal rule on a uniform mesh with n_h intervals. Data for this problem appears in Table 3.1.

Table 3.1: Hanging chain problem data

Linear inequality constraints	0
Nonlinear equality constraints	1
Nonlinear inequality constraints	0
Nonzeros in $\nabla^2 f(x)$	$3n_h$
Nonzeros in $c'(x)$	$5n_h$

Performance

Results for the AMPL implementation are summarized in Table 3.2 with $a = 1$, $b = 3$, and $L = 4$. The starting point is the quadratic

$$x(t) = (2|b - a|)t(t - 2t_m) + a,$$

where $t_m = 0.25$ if $b > a$ and $t_m = 0.75$ otherwise, evaluated at the mesh points. This choice is convex and satisfies the boundary data. The control function u is set to x' . The optimal chain is shown in Figure 3.1.

4 Shape Optimization of a Cam

Maximize the area of the valve opening for one rotation of a convex cam with constraints on the curvature and on the radius of the cam.

Formulation

The formulation of this problem is due to Anitescu and Serban [1]. We assume that the shape of the cam is circular over an angle of $\frac{6}{5}\pi$ of its circumference, with radius r_{\min} . The design variables r_i , $i = 1, \dots, n$, represent the radius of the cam at equally spaced angles distributed over an angle of $\frac{2}{5}\pi$. We maximize the area of the valve opening by maximizing

$$f(r) = \pi r_v^2 \left(\frac{1}{n} \sum_{i=1}^n r_i \right)$$

subject to the constraints on r . The design parameter r_v is related to the geometry of the valve. We also require that $r_{\min} \leq r_i \leq r_{\max}$. The requirement that the cam be convex is expressed by requiring that

$$\text{area}(r_{i-1}, r_{i+1}) \leq \text{area}(r_{i-1}, r_i) + \text{area}(r_i, r_{i+1}),$$

where $\text{area}(r_i, r_j)$ is the area of the triangle defined by the origin and the points r_i and r_j on the cam surface. This convexity constraint can also be expressed as

$$2r_{i-1}r_{i+1} \cos(\theta) \leq r_i(r_{i-1} + r_{i+1}), \quad i = 0, \dots, n+1,$$

where $r_{-1} = r_0 = r_{\min}$, $r_{n+1} = r_{\max}$, $r_{n+2} = r_n$ and $\theta = 2\pi/5(n+1)$. The curvature requirement is expressed by

$$-\alpha \leq \left(\frac{r_{i+1} - r_i}{\theta} \right) \leq \alpha, \quad i = 0, \dots, n.$$

This is a departure from [1], where the curvature constraint was expressed in terms of $(r_{i+1} - r_i)^2$. Data for this problem appears in Table 4.1.

Table 4.1: Optimal design of a cam problem data

Variables	n
Constraints	$2n + 2$
Bounds	n
Linear equality constraints	0
Linear inequality constraints	$n + 1$
Nonlinear equality constraints	0
Nonlinear inequality constraints	$n + 1$
Nonzeros in $\nabla^2 f(x)$	0
Nonzeros in $c'(x)$	$5n$

We follow [1] and use $r_{\min} = 1.0$ and $r_{\max} = 2.0$ for the bounds on r , $r_v = 1.0$ in the area of the valve, and $\alpha = 1.5$ in the curvature constraint. Since the optimal cam shape is symmetric, we consider only half of the design angle. The problem was originally [1] formulated for the full angle of $\frac{4}{5}\pi$.

Performance

Results for the AMPL implementation are summarized in Table 4.2. We use a starting guess of $r_i \equiv (r_{\min} + r_{\max})/2$. The cam shape for $\alpha = 1.5$ appears in Figure 4.1. We note that the number of active constraints increases with α up to a threshold of $\alpha_1 \approx 3.0$, after which increasing α does not change the optimal solution.

Figure 4.1: Cam shape for $\alpha = 1.5$.

5 Isometrization of α -pinene

Determine the reaction coefficients in the thermal isometrization of α -pinene. The linear kinetic model [6] is

$$\begin{aligned} y_1' &= -(\theta_1 + \theta_2)y_1 \\ y_2' &= \theta_1 y_1 \\ y_3' &= \theta_2 y_1 - (\theta_3 + \theta_4)y_3 + \theta_5 y_5 \\ y_4' &= \theta_3 y_3 \\ y_5' &= \theta_4 y_3 - \theta_5 y_5, \end{aligned} \tag{5.1}$$

where $\theta_i \geq 0$ are the reaction coefficients. Initial conditions for (5.1) are known. The problem is to minimize

$$\sum_{j=1}^8 \|y(\tau_j; \theta) - z_j\|^2, \tag{5.2}$$

where z_j are concentration measurements for y at time points τ_1, \dots, τ_8 .

Formulation

Our formulation of the α -pinene problem as an optimization problem follows [21, 3]. We use a k -stage collocation method, a uniform partition with n_h subintervals of $[0, \tau_8]$, and the standard [2, pages 247–249] basis representation,

$$v_i + \sum_{j=1}^k \frac{(t - t_i)^j}{j! h^{j-1}} w_{ij}, \quad t \in [t_i, t_{i+1}],$$

for the components of the solution y of (5.1). The constraints in the optimization problem are the initial conditions in (5.1), the continuity conditions, and the collocation equations. The continuity equations at each interior grid point are a set of $5(n_h - 1)$ linear equations. The collocation equations are a set of $5kn_h$ nonlinear equations obtained by requiring that the collocation approximation satisfy (5.1) at the collocation points. Data for this problem appears in Table 5.1.

Table 5.1: Isometrization of α -pinene data

Variables	$5(k+1)n_h + 5$

LANCELOT stops with the message *step got too small*, near the solution for $n_h \leq 50$. MINOS fails completely on $n_h = 200$ with *unbounded (or badly scaled) problem*, while SNOPT manages a *[p]rimal feasible solution*, which could not satisfy dual feasibility for both $n_h = 50, 200$.

Figure 5.1: Solution and data for the α -pinene problem

6 Marine Population Dynamics

Given estimates of the abundance of the population of a marine species at each stage (for example, nauplius, juvenile, adult) as a function of time, determine stage specific growth and mortality rates. The model for the population dynamics of the n_s -stage population is

$$y'_j = g_{j-1}y_{j-1} - (m_j + g_j)y_j, \quad 1 \leq j \leq n_s, \quad (6.1)$$

where m_i and g_i are the unknown mortality and growth rates at stage i with $g_0 = g_{n_s} = 0$. This model assumes that the species eventually dies or grows into the next stage, with the implicit assumption that the species cannot skip a stage. Initial conditions for the differential equations are unknown, since the stage abundance measurements at the initial time might also be contaminated with experimental error. We minimize the error between computed and observed data,

$$\sum_{j=1}^{n_m} \|y(\tau_j; m, g) - z_j\|^2,$$

where z_j are the stage abundance measurements. This problem is based on the work of Rothschild, Sharov, Kearsley, and Bondarenko [19].

Formulation

Our formulation of the marine population dynamics uses a k -stage collocation method, a uniform partition with n_h subintervals of $[0, \tau_{n_m}]$, and the standard [2, pages 247–249] basis representation,

$$v_i + \sum_{j=1}^k \frac{(t - t_i)^j}{j! h^{j-1}} w_{ij}, \quad t \in [t_i, t_{i+1}],$$

for the components of the solution y of (6.1). The constraints in the optimization problem are the continuity conditions and the collocation equations. The continuity equations are a set of $n_s(n_h - 1)$ linear equations. The collocation equations are a set of $k n_s n_h$ nonlinear equations obtained by requiring that the collocation approximation satisfy (6.1) at the collocation points $\xi_{ij} = t_i + h\rho_j$ for $i = 1, \dots, n_h$ and $j = 1, \dots, k$.

Table 6.1: Marine population dynamics problem data

Variables	$(k + 1)n_s n_h + 2n_s - 1$
Constraints	$(k + 1)n_s n_h - n_s$
Bounds	$2n_s - 1$
Linear equality constraints	$n_s(n_h - 1)$
Linear inequality constraints	0
Nonlinear equality constraints	$k n_s n_h$
Nonlinear inequality constraints	0
Nonzeros in $\nabla^2 f(x)$	$(k + 1)^2 n_s n_m$
Nonzeros in $c'(x)$	$(2k + 1)(k + 2)n_s n_h$

The parameters in the problem are the $n_s n_h$ initial conditions, the n_s mortality rates, the $n_s - 1$ growth rates, and the $(k + 1)n_s n_h$ basis parameters in the representation of the collocation approximation. Data for this problem appears in Table 6.1.

We do not impose any initial conditions on the differential equations, since initial measurements are usually contaminated with experimental error. Introducing these extra degrees of freedom into the problem formulation should allow solvers to find a better fit to the data. A significant difference between this problem and other parameter estimation problems is that the population dynamics data usually contains large observation errors.

Performance

We provide results for the AMPL formulation with $k = 2$ in Table 6.2. We use a simulated dataset with $n_s = 8$ stages. The initial basis parameters are chosen so that the collocation approximation is piecewise constant and interpolates the data.

† Errors or warnings. ‡ Timed out.

LANCELOT returns the message *step got too small* for the values of n_h for which it terminates within 3,600 wall-clock seconds. The intermediate solution returned by LANCELOT upon termination is in close agreement with the optimal solutions returned by the other solvers. MINOS makes no progress with $n_h = 200$, returning with the error *unbounded (or badly scaled) problem*.

The graph on the left of Figure 6.1 shows the populations for stages 1, 2, 5, and 6, while the graph on the right shows the populations for stages 3, 4, 7, and 8. In both cases, the fit between the model and the data is not always tight.

For this problem we are using a relatively small number of collocation points ($k = 2$), since in this case the number of parameters grows quickly with the number of stages. The quality of the solution does not seem to be affected, at least as measured by the population

curves and the mortality and growth parameters.

Figure 6.1: Marine populations for stages 1, 2, 5, 6 (left) and 3, 4, 7, 8 (right)

Figure 6.2 plots the mortality and growth parameters for the eight stages. Mortality parameters are marked *, while growth parameters are marked \circ . The mortality parameters for stages 5 and 6 are not zero, but they are on the order of 10^{-3} and 10^{-9} , respectively.

Figure 6.2: Mortality (*) and growth (o) parameters for the marine populations stages

7 Flow in a Channel

Analyze the flow of a fluid during injection into a long vertical channel, assuming that the flow is modeled by the boundary value problem

$$\begin{aligned} u'''' &= R(u'u'' - uu'''), & 0 \leq t \leq 1, \\ u(0) &= 0, \quad u(1) = 1, \quad u'(0) = u'(1) = 0, \end{aligned} \quad (7.1)$$

where u is the potential function, u' is the tangential velocity of the fluid, and R is the Reynolds number.

Formulation

We use a k -stage collocation method to formulate this problem as an optimization problem with a constant merit function and equality constraints representing the solution of (7.1). We use a uniform partition with n_h subintervals of $[0, 1]$, and the standard [2, pages 247–249] basis representation,

$$u(t) = \sum_{j=1}^m \frac{(t - t_i)^{j-1}}{(j-1)!} v_{ij} + \sum_{j=1}^k \frac{(t - t_i)^{j+m-1}}{(j+m-1)! h^{j-1}} w_{ij}, \quad t \in [t_i, t_{i+1}],$$

for u . Note that $u \in C^{m-1}[0, 1]$, where $m = 4$ is the order of the differential equation.

The constraints in the optimization problem are the initial conditions in (7.1), the continuity conditions, and the collocation equations. There are $m = 4$ initial conditions. The continuity equations are a set of $m(n_h - 1)$ linear equations. The collocation equations are a set of $k n_h$ nonlinear equations obtained by requiring that u satisfy (7.1) at the collocation points $\xi_{ij} = t_i + h\rho_j$ for $i = 1, \dots, n_h$ and $j = 1, \dots, k$. The collocation points ρ_j are the roots of the k th degree Legendre polynomial. The parameters in the optimization problem are the $(m + k)n_h$ parameters v_{ij} and w_{ij} in the representation of u . Data for this problem appears in Table 7.1.

Table 7.1: Flow in a channel problem data

Variables	$(k + 4)n_h$
Constraints	$(k + 4)n_h$

LANCELOT is unable to solve even simple versions of the problem, advancing very slowly toward the solution (as judged from the value of the merit function).

Figure 7.1: Tangential velocity u' for Reynolds numbers $R = 0, 10^2, 10^4$

8 Robot Arm

Minimize the time taken for a robot arm to travel between two points.

Formulation

This problem originated in the thesis of Monika Mössner-Beigel (Heidelberg University). In her formulation the arm of the robot is a rigid bar of length L that protrudes a distance ρ from the origin to the gripping end and sticks out a distance $L - \rho$ in the opposite direction. If the pivot point of the arm is the origin of a spherical coordinate system, then the problem can be phrased in terms of the length ρ of the arm from the pivot, the horizontal and vertical angles (θ, ϕ) from the horizontal plane, the controls $(u_\rho, u_\theta, u_\phi)$, and the final time t_f . Bounds on the length and angles are

$$\rho(t) \in [0, L], \quad |\theta(t)| \leq \pi, \quad 0 \leq \phi(t) \leq \pi,$$

and for the controls,

$$|u_\rho| \leq 1, \quad |u_\theta| \leq 1, \quad |u_\phi| \leq 1.$$

The equations of motion for the robot arm are

$$L\rho'' = u_\rho, \quad I_\theta\theta'' = u_\theta, \quad I_\phi\phi'' = u_\phi, \quad (8.1)$$

where I is the moment of inertia, defined by

$$I_\theta = \frac{((L - \rho)^3 + \rho^3)}{3} \sin(\phi)^2, \quad I_\phi = \frac{((L - \rho)^3 + \rho^3)}{3}.$$

The boundary conditions are

$$\begin{aligned} \rho(0) = \rho(t_f) = 4.5, \quad \theta(0) = 0, \quad \theta(t_f) = \frac{2\pi}{3}, \quad \phi(0) = \phi(t_f) = \frac{\pi}{4}, \\ \rho'(0) = \theta'(0) = \phi'(0) = \rho'(t_f) = \theta'(t_f) = \phi'(t_f) = 0. \end{aligned}$$

This model ignores the fact that the spherical coordinate reference frame is a noninertial frame and should have terms for Coriolis and centrifugal forces.

Implementation

In the implementation of Vanderbei [22] the controls u are eliminated by substitution, and thus the equality constraints in (8.1) become the inequalities

$$|L\rho''| \leq 1, \quad |I_\theta\theta''| \leq 1, \quad |I_\phi\phi''| \leq 1.$$

In this implementation (8.1) is expressed in terms of a first-order system with the additional variables ρ' , θ' , and ϕ' . Discretization is done with a uniform time step and the trapezoidal rule over n_h intervals. Data for this problem is shown in Table 8.1.

Table 8.1: Robot arm problem data

Nonzeros in $c'(x)$	$36n_h$

Performance

Results for the AMPL implementation appear in Table 8.2. All solvers were given the same initial values. The initial values for ρ and ϕ were set to the functions $\rho \equiv 4.5$ and $\phi \equiv \pi/4$ evaluated at the grid points. Similarly, initial values for θ were set to the discrete version of the parabola

$$\theta(t) = \frac{2\pi}{3} \left(\frac{t}{t_f} \right)^2,$$

which matches three of the boundary conditions. The initial values for all the controls were set to zero, and $t_f = 1$ initially.

† Errors or warnings. ‡ Timed out.

LANCELOT reports that it *could not find a feasible solution* for any of the versions we try for this implementation. For $n_h = 100$, SNOPT encounters difficulties, which it describes as an *error evaluating nonlinear expressions*.

Figure 8.1 shows the variables ρ , θ , ϕ for the robot arm as a function of time. We also show in Figure 8.2 the controls u_ρ , u_θ , u_ϕ as a function of time. Note that the controls for the robot arm are bang-bang. Also note that the functions ρ , θ , ϕ for the robot arm are continuously differentiable, but since the second derivatives are directly proportional to the controls, the second derivatives are piecewise continuous.

Figure 8.1: Variables ρ , θ , ϕ for the robot arm as a function of time

Figure 8.2: Control variables u_ρ , u_θ , u_ϕ for the robot arm as a function of time

9 Particle Steering

Minimize the time taken for a particle, acted upon by a thrust of constant magnitude, to achieve a given altitude and terminal velocity.

Formulation

The equations of motion are

$$\ddot{y}_1 = a \cos(u), \quad \ddot{y}_2 = a \sin(u), \quad (9.1)$$

where (y_1, y_2) is the position of the particle, u is the control angle with

$$|u(t)| \leq \frac{\pi}{2},$$

and a is the constant magnitude of thrust. The particle is initially at rest so that

$$y_1(0) = y_2(0) = \dot{y}_1(0) = \dot{y}_2(0) = 0.$$

The problem is to minimize the travel time t_f so that the particle achieves a given height $y_2(t_f)$ and terminal velocity $(\dot{y}_1(t_f), \dot{y}_2(t_f))$.

This is a classical (see Bryson and Ho [7, pages 59–62]) problem in dynamic optimization. We use $a = 100$ for the magnitude of thrust and the boundary conditions [4]

$$y_2(t_f) = 5, \quad \dot{y}_1(t_f) = 45, \quad \dot{y}_2(t_f) = 0.$$

Discretization is done using a uniform time step and the trapezoidal rule for the integration of the system over n_h intervals. Data for this problem is shown in Table 9.1.

Initial values for y_2 , $y_4 = \dot{y}_2$, and u are set to zero. The initial value for the final time is $t_f = 1$. Plots of the height y_2 and control u as a function of the horizontal position y_1 are in Figure 9.1.

Only LANCELOT returns an error here, for $n_h = 400$, of *step got too small*. Even so, it comes near to the optimal solution value.

Figure 9.1: Height and control as a function of position for the particle steering problem

10 Goddard Rocket

Maximize the final altitude of a vertically launched rocket, using the thrust as a control and given the initial mass, the fuel mass, and the drag characteristics of the rocket.

Formulation

This is a classical problem in dynamic optimization that is typical of control problems with a singular arc. See Bryson [8, pages 392–394] for background information. The equations of motion for the rocket are

$$h' = v, \quad v' = \frac{T - D(h, v)}{m} - g(h), \quad m' = -\frac{T}{c}, \quad (10.1)$$

where h is the altitude from the center of the earth, v is the vertical velocity, T is the rocket thrust, D is the aerodynamic drag, g is the gravitational force, and c is a constant that measures the impulse of the rocket fuel. The thrust must satisfy

$$0 \leq T(t) \leq T_{\max}.$$

The drag and the gravitational force are defined by

$$D(h, v) = D_c v^2 \exp\left(-h_c \left(\frac{h - h(0)}{h(0)}\right)\right), \quad g(h) = g_0 \left(\frac{h(0)}{h}\right)^2,$$

where D_c and h_c are constants, and g_0 is the gravitational force at the earth's surface. The rocket is initially at rest ($v(0) = 0$), and the mass at the end of the flight is a fraction of the initial mass,

$$m(t_f) = m_c m(0),$$

where t_f is the flight time and m_c is a constant. In addition to the bounds on the thrust, there are bounds

$$m(t_f) \leq m(t) \leq m(0), \quad h(t) \geq h(0), \quad v(t) \geq 0,$$

on the mass, altitude, and velocity of the rocket. These bounds are a direct consequence of the equations of motion (10.1).

The equations of motion can be made dimension free by scaling the equations and choosing the model parameters in terms of $h(0)$, $m(0)$, and g_0 . We follow [8] and use

$$T_{\max} = 3.5 g_0 m(0), \quad D_c = \frac{1}{2} v_c \frac{m(0)}{g_0}, \quad c = \frac{1}{2} (g_0 h(0))^{1/2}.$$

With these choices we can assume, without loss of generality, that $h(0) = m(0) = g_0 = 1$. We also follow [8] and choose

$$h_c = 500, \quad m_c = 0.6, \quad v_c = 620.$$

We discretize the equations of motion with the trapezoidal rule, and a uniform mesh with n_h intervals. Data for this problem appears in Table 10.1.

Performance

Results for the AMPL implementation are shown in Table 10.2. For starting points we use $t_f = 1$ and the functions $h = 1$,

$$v(t) = \frac{t}{t_f} \left(1 - \frac{t}{t_f} \right), \quad m(t) = (m_f - m_0) \left(\frac{t}{t_f} \right) + m_0,$$

evaluated at the grid points. The initial value for the thrust is $T = T_{\max}/2$.

For the rocket problem with $n_h = 200, 400$, MINOS makes no progress, declaring it to be an *unbounded (or badly scaled) problem*.

Figure 10.1 shows the altitude and mass of the rocket as a function of time. Note that altitude increases until a maximum altitude of $h = 1.01$ is reached, while the mass of the rocket steadily decreases until the final mass of $m(t_f) = 0.6$ is reached at $t = 0.073$.

Figure 10.2 shows the velocity and thrust as a function of time. The thrust is bang-singular-bang, with the region of singularity occurring when

$$0 < T(t) < T_{\max}.$$

This figure shows that the optimal flight path involves using maximal thrust until $t = 0.022$, and no thrust for $t \geq 0.073$, at which point the final mass is reached, and the rocket coasts to its maximal altitude. The oscillations that appear at the point of discontinuity in the thrust parameter can be removed by using more grid points.

Figure 10.1: Altitude and mass for the Goddard rocket problem

Figure 10.2: Velocity and thrust for the Goddard rocket problem

11 Hang Glider

Maximize the final horizontal position of a hang glider while in the presence of a thermal updraft.

Formulation

The formulation of this problem follows [9]. The equations of motion for the hang glider are

$$x'' = \frac{1}{m}(-L \sin(\eta) - D \cos(\eta)), \quad y'' = \frac{1}{m}(L \cos(\eta) - D \sin(\eta)) - g, \quad (11.1)$$

where (x, y) is the position of the glider, m is the mass of the glider, g is the gravitational constant, and the function η is defined by

$$\sin(\eta) = \frac{w(x, y')}{v(x, x', y')}, \quad \cos(\eta) = \frac{x'}{v(x, x', y')},$$

where

$$v(x, x', y') = \sqrt{x'^2 + w(x, y')^2}, \quad w(x, y') = y' - u(x),$$

$$u(x) = u_c(1 - r(x)) \exp(-r(x)), \quad r(x) = \left(\frac{x}{r_c} - 2.5\right)^2,$$

and constants $u_c = 2.5$ and $r_c = 100$. The updraft function u is positive in a neighborhood of $x = 2.5 r_c$ but drops to zero exponentially away from $x = 2.5 r_c$. The functions D and L are defined by

$$D(x, x', y', c_L) = \frac{1}{2} (c_0 + c_1 c_L^2) \rho S v(x, x', y')^2, \quad L(x, x', y', c_L) = \frac{1}{2} c_L \rho S v(x, x', y')^2,$$

where S is the wing area, ρ is the air density, c_L is the aerodynamic lift coefficient, and $c_0 + c_1 c_L^2$ is the drag coefficient. For this glider

$$c_0 = 0.034, \quad c_1 = 0.069662, \quad S = 14, \quad \rho = 1.13.$$

The aerodynamic lift coefficient c_L must satisfy the bounds

$$0 \leq c_L(t) \leq c_{\max},$$

and we also impose the natural bounds $x \geq 0$ and $x' \geq 0$. In this problem $c_{\max} = 1.4$, $m = 100$, $g = 9.81$, and the boundary conditions are

$$x(0) = 0, \quad y(0) = 1000, \quad y(t_f) = 900,$$

$$x'(0) = x'(t_f) = 13.23, \quad y'(0) = y'(t_f) = -1.288.$$

Discretization is done with a uniform time step and the trapezoidal rule over n_h intervals. Data for this problem is shown in Table 11.1.

Performance

Results for the AMPL implementation are shown in Table 11.2. For starting points we use $t_f = 1$ and the functions $x' = x'(0)$, $y' = y'(0)$, and

$$x(t) = x(0) + x'(0) \left(\frac{t}{t_f} \right), \quad y(t) = y(0) + (y(t_f) - y(0)) \left(\frac{t}{t_f} \right),$$

evaluated at the grid points. The initial value for the control is $c_L(t) = c_{\max}$.

MINOS fails to produce a solution for any of the problem versions we present it, declaring each an *infeasible problem (or bad starting guess)*.

Figure 11.1 shows the altitude and control function c_L as a function of time. The glider starts at an altitude of $y(0) = 1000$ and descends until the glider meets the updraft centered at $x = 250$. As a result the glider climbs and then descends to the desired final altitude of $y(t_f) = 900$ at time $t_f = 105$.

Figure 11.1: Altitude and control c_L for the hang glider problem

Figure 11.2 shows velocities x' and y' as a function of time. Note, in particular, the erratic behavior of the velocities while the control is in the bang-region where $c_L(t) = c_{\max}$.

12 Catalytic Cracking of Gas Oil

Determine the reaction coefficients for the catalytic cracking of gas oil into gas and other byproducts. The nonlinear model [21] that describes the process is

$$\begin{aligned} y_1' &= -(\theta_1 + \theta_3)y_1^2 \\ y_2' &= \theta_1 y_1^2 - \theta_2 y_2 \end{aligned} \quad (12.1)$$

with coefficients $\theta_i \geq 0$ for $i = 1, \dots, 3$. Initial conditions for (12.1) are known. The problem is to minimize

$$\sum_{j=1}^{21} \|y(\tau_j; \theta) - z_j\|^2,$$

where z_j are concentration measurements for y at time points τ_1, \dots, τ_{21} .

Formulation

Our formulation of the catalytic cracking of gas oil problem as an optimization problem follows [21, 3]. We use a k -stage collocation method, a uniform partition of the interval $[0, \tau_{20}]$ with n_h intervals, and the standard [2, pages 247249] basis representation,

$$v_i + \sum_{j=1}^k \frac{(t - t_i)^j}{j! h^{j-1}} w_{ij}, \quad t \in [t_i, t_{i+1}],$$

for the components of the solution (y_1, y_2) of (12.1). The constraints in the optimization problem are the initial conditions in (12.1), the continuity conditions, and the collocation equations. The continuity equations are a set of $2(n_h - 1)$ linear equations. The collocation equations are a set of $2kn_h$ nonlinear equations obtained by requiring that the collocation approximation satisfy (12.1) at the collocation points. Data for this problem appears in Table 12.1.

Table 12.1: Catalytic cracking of gas oil data

13 Methanol to Hydrocarbons

Determine the reaction coefficients for the conversion of methanol into various hydrocarbons. The nonlinear model [12, 17] that describes the process is

$$\begin{aligned} y_1' &= - \left(2\theta_2 - \frac{\theta_1 y_2}{(\theta_2 + \theta_5) y_1 + y_2} + \theta_3 + \theta_4 \right) y_1 \\ y_2' &= \frac{\theta_1 y_1 (\theta_2 y_1 - y_2)}{(\theta_2 + \theta_5) y_1 + y_2} + \theta_3 y_1 \\ y_3' &= \frac{\theta_1 y_1 (y_2 + \theta_5 y_1)}{(\theta_2 + \theta_5) y_1 + y_2} + \theta_4 y_1 \end{aligned} \tag{13.1}$$

with coefficients $\theta_i \geq 0$ for $i = 1, \dots, 5$. Initial conditions for (13.1) are known. The problem is to minimize

$$\sum_{j=1}^{16} \|y(\tau_j; \theta) - z_j\|^2,$$

where z_j are concentration measurements for y at time points τ_1, \dots, τ_{16} .

Formulation

Our formulation of the methanol-to-hydrocarbons problem as an optimization problem follows [21, 3]. We use a k -stage collocation method, a uniform partition of the interval $[0, \tau_{16}]$ with n_h intervals, and the standard [2, pages 247-249] basis representation,

$$v_i + \sum_{j=1}^k \frac{(t - t_i)^j}{j! h^{j-1}} w_{ij}, \quad t \in [t_i, t_{i+1}],$$

for the components of the solution (y_1, y_2, y_3) of (13.1). The constraints in the optimization problem are the initial conditions in (13.1), the continuity conditions, and the collocation equations. The continuity equations are a set of $3(n_h - 1)$ linear equations. The collocation equations are a set of $3kn_h$ nonlinear equations obtained by requiring that the collocation approximation satisfy (13.1) at the collocation points. Data for this problem appears in Table 13.1.

14 Catalyst Mixing

Determine the optimal mixing policy of two catalysts along the length of a tubular plug flow reactor involving several reactions.

Formulation

The nonlinear model [23] that describes the reactions is

$$\begin{aligned}x_1'(t) &= u(t)(10x_2(t) - x_1(t)) \\x_2'(t) &= u(t)(x_1(t) - 10x_2(t)) - (1 - u(t))x_2(t).\end{aligned}\tag{14.1}$$

Initial conditions for (14.1) are $x_1(0) = 1$ and $x_2(0) = 0$. The control variable u represents the mixing ratio of the catalysts and must satisfy the bounds

$$0 \leq u(t) \leq 1.$$

The problem is to minimize

$$-1 + x_1(t_f) + x_2(t_f),\tag{14.2}$$

where the final time is fixed at $t_f = 1$.

We discretize the control and state variables along a uniform mesh with n_h intervals and with the standard trapezoidal rule. Data for this problem appears in Table 14.1.

Table 14.1: Catalyst mixing data

Variables	$3(n_h + 1)$
Constraints	$2n_h$

Linear inequality constraints	0
Nonlinear equality constraints	$2n_h$
Nonlinear inequality constraints	0
Nonzeros in $\nabla^2 f(x)$	0
Nonzeros in $c'(x)$	$12n_h$

Performance

Results for the AMPL implementation are shown in Table 14.2. For starting points we use $u = 0$, $x_1 = 1$, and $x_2 = 0$ evaluated at the grid points.

The catalyst mixing problem is a typical bang-singular-bang problem. The singularity leads to nonunique values of the control in the singular region, and thus it is possible to obtain different values for the control. Figure 14.1 shows the controls obtained by two different solvers.

The results in Table 14.2 show that all the solvers are successful for $n_h \geq 100$ but that the objective function value fluctuates somewhat. This is probably due to the bang-singular-bang nature of the problem. The most common approach to dealing with singular control

problems is to add a penalty to the objective function that leads to a smooth control, for example,

$$\alpha \int_0^1 u'(t)^2 dt$$

for some positive value of α . Values of $\alpha \geq 1$ seems to work well for this problem, but an appropriate value is difficult to find.

Figure 14.1: Controls obtained by two different solvers for the catalyst mixing problem

15 Elastic-Plastic Torsion

Determine the stress potential in an infinitely long cylinder when torsion is applied.

Formulation

The elastic-plastic torsion problem [15, pages 41–46] can be formulated in terms of the cross-section \mathcal{D} of the cylinder, and the torsion angle c per unit length. The stress potential u minimizes the quadratic $q : K \mapsto \mathbb{R}$,

$$q(v) = \int_{\mathcal{D}} \left\{ \frac{1}{2} \|\nabla v(x)\|^2 - c v(x) \right\} dx,$$

over the convex set K , where

$$K = \{v \in H_0^1(\mathcal{D}) : |v| \leq \text{dist}(x, \partial\mathcal{D}), x \in \mathcal{D}\},$$

$\text{dist}(x, \partial\mathcal{D})$ is the distance from x to the boundary of \mathcal{D} , and $H_0^1(\mathcal{D})$ is the space of functions with gradients in $L^2(\mathcal{D})$ that vanish on the boundary of \mathcal{D} .

A finite element approximation to the elastic-plastic torsion problem is obtained by triangulating \mathcal{D} and minimizing q over the space of piecewise linear functions with values $v_{i,j}$ at the vertices of the triangulation. We follow [15, 3] by choosing $\mathcal{D} = [0, 1] \times [0, 1]$, and using a triangulation with, respectively, n_x and n_y internal grid points in the coordinate directions. Data for this problem appears in Table 15.1.

Table 15.1: Elastic-plastic torsion problem data

Nonzeros in $c'(x)$	0

Performance

We provide results for the AMPL formulation with $c = 5$ in Table 15.2. For these results we fix $n_x = 50$ and vary n_y . The starting guess is the function $\text{dist}(x, \partial\mathcal{D})$ evaluated at the grid nodes. Figure 15.1 shows the potential in the torsion problem with $c = 5$. The number of active constraints in this problem increases with c . Also

$$\lim_{c \rightarrow \infty} v_c(x) = \text{dist}(x, \partial\mathcal{D}),$$

where v_c is the potential as a function of c .

16 Journal Bearing

Given the eccentricity ϵ of the journal bearing, find the pressure distribution in the lubricant separating the shaft from the bearing.

Formulation

The journal bearing problem [10] requires determining the pressure between two circular cylinders of length L and radii R and $R + c$. The separation between the cylinders is ϵc , where ϵ is the eccentricity. The pressure v minimizes the quadratic $q : K \mapsto \mathbb{R}$,

$$q(v) = \int_{\mathcal{D}} \left\{ \frac{1}{2} w_q(x) \|\nabla v(x)\|^2 - w_l(x) v(x) \right\} dx,$$

over the convex set K , where $\mathcal{D} = (0, 2\pi) \times (0, 2b)$,

$$K = \{v \in H_0^1(\mathcal{D}) : v \geq 0\},$$

$H_0^1(\mathcal{D})$ is the space of functions with gradients in $L^2(\mathcal{D})$ that vanish on the boundary of \mathcal{D} , and the functions $w_q : \mathcal{D} \mapsto \mathbb{R}$ and $w_l : \mathcal{D} \mapsto \mathbb{R}$ are defined by

$$w_q(\xi_1, \xi_2) = (1 + \epsilon \cos \xi_1)^3, \quad w_l(\xi_1, \xi_2) = \epsilon \sin \xi_1,$$

with $\epsilon \in (0, 1)$ the eccentricity of the bearing.

A finite element approximation to the journal bearing problem is obtained by triangulating \mathcal{D} and minimizing q over the space of piecewise linear functions with values $v_{i,j}$ at the vertices of the triangulation. We follow [3] by using a triangulation with, respectively, n_x and n_y internal grid points in the coordinate directions. Data for this problem appears in Table 16.1.

Nonzeros in $c'(x)$	0

Performance

We provide results with the AMPL formulation in Table 16.2 with $b = 10$ and $\epsilon = 0.1$. For these results we fix $n_x = 50$ and vary n_y . The starting guess is the function $\max\{\sin(x), 0\}$ evaluated at the grid nodes. Figure 16.1 shows the pressure distribution for the journal bearing problem.

17 Minimal Surface with Obstacle

Find the surface with minimal area, given boundary conditions, and above an obstacle.

Formulation

Plateau's problem is to determine the surface of minimal area with a given closed curve in \mathbb{R}^3 as boundary. We assume that the surface can be represented in nonparametric form $v : \mathbb{R}^2 \mapsto \mathbb{R}$, and we add the requirement that $v \geq v_L$ for some obstacle v_L . The solution of this obstacle problem [13] minimizes the function $f : K \mapsto \mathbb{R}$,

$$f(v) = \int_{\mathcal{D}} (1 + \|\nabla v(x)\|^2)^{1/2} dx,$$

over the convex set K , where

$$K = \{v \in H^1(\mathcal{D}) : v(x) = v_D(x) \text{ for } x \in \partial\mathcal{D}, \quad v(x) \geq v_L(x) \text{ for } x \in \mathcal{D}\},$$

$H^1(\mathcal{D})$ is the space of functions with gradients in $L^2(\mathcal{D})$, the function $v_D : \partial\mathcal{D} \mapsto \mathbb{R}$ defines the boundary data, and $v_L : \mathcal{D} \mapsto \mathbb{R}$ is the obstacle. We assume that $v_L \leq v_D$ on the boundary $\partial\mathcal{D}$.

A finite element approximation to the minimal surface problem is obtained by triangulating \mathcal{D} and minimizing f over the space of piecewise linear functions with values $v_{i,j}$ at the vertices of the triangulation. We set $\mathcal{D} = [0, 1] \times [0, 1]$ and use a triangulation with, respectively, n_x and n_y internal grid points in the coordinate directions. Data for this problem appears in Table 16.1.

Table 17.1: Minimal surface problem data

Variables	$n_x n_y$
Constraints	0
Bounds	$n_x n_y$

Linear inequality constraints	0
Nonlinear equality constraints	0
Nonlinear inequality constraints	0
Nonzeros in $\nabla^2 f(x)$	$5n_x n_y - 2(n_x + n_y)$
Nonzeros in $c'(x)$	0

Performance

We provide results for the AMPL formulation in Table 17.2. For these results we fix $n_x = 50$ and vary n_y . The starting guess is the function $1 - (2x - 1)^2$ evaluated at the grid nodes. We used boundary data

$$v_D(x, y) = \begin{cases} 1 - (2x - 1)^2, & y = 0, 1 \\ 0, & \text{otherwise,} \end{cases}$$

and the obstacle

$$v_L(x, y) = \begin{cases} 1 & \text{if } |x - \frac{1}{2}| \leq \frac{1}{4}, |y - \frac{1}{2}| \leq \frac{1}{4} \\ 0, & \text{otherwise.} \end{cases}$$

Figure 17.1 shows the minimal surface for this data.

Acknowledgments

Version 1.0 of the COPS problems was developed by Alexander Bondarenko, David Bortz, Liz Dolan, and Michael Merritt. Their contributions were essential because, in many cases, version 2.0 of the problems are closely related to the original version.

Alex Bondarenko, Nick Gould, Sven Leyffer and Bob Vanderbei contributed interesting and spirited discussions on problem formulation, while Bob Fourer and David Gay generously shared their AMPL expertise with us. Finally, we thank Hans Mittelmann for paving the way for COPS with his benchmarking work.
