## Part 2: Linesearch methods for unconstrained optimization

Nick Gould (RAL)

 $\text{minimize} \quad f(x) \\
 x \in \mathbb{R}^n$ 

MSc course on nonlinear optimization

#### ITERATIVE METHODS

- $\odot$  in practice very rare to be able to provide explicit minimizer
- $\odot$  iterative method: given starting "guess"  $x_0$ , generate sequence

$$\{x_k\}, k = 1, 2, \dots$$

- AIM: ensure that (a subsequence) has some favourable limiting properties:
- $\diamond$  satisfies first-order necessary conditions
- $\diamond\,$  satisfies second-order necessary conditions

Notation: 
$$f_k = f(x_k), g_k = g(x_k), H_k = H(x_k).$$

## UNCONSTRAINED MINIMIZATION

 $\text{minimize } f(x) \\
 x \in \mathbb{R}^n$ 

where the **objective function**  $f: \mathbb{R}^n \longrightarrow \mathbb{R}$ 

- $\odot$  assume that  $f\in C^1$  (sometimes  $C^2)$  and Lipschitz
- $\odot$  often in practice this assumption violated, but not necessary

#### LINESEARCH METHODS

- $\odot$  calculate a **search direction**  $p_k$  from  $x_k$
- o ensure that this direction is a descent direction, i.e.,

$$g_k^T p_k < 0 \text{ if } g_k \neq 0$$

so that, for small steps along  $p_k$ , the objective function **will** be reduced

 $\odot$  calculate a suitable **steplength**  $\alpha_k > 0$  so that

$$f(x_k + \alpha_k p_k) < f_k$$

- $\circ$  computation of  $\alpha_k$  is the **linesearch**—may itself be an iteration
- $\odot\,$  generic linesearch method:

$$x_{k+1} = x_k + \alpha_k p_k$$

### STEPS MIGHT BE TOO LONG

The objective function  $f(x)=x^2$  and the iterates  $x_{k+1}=x_k+\alpha_k p_k$  generated by the descent directions  $p_k=(-1)^{k+1}$  and steps  $\alpha_k=2+3/2^{k+1}$  from  $x_0=2$ 

## PRACTICAL LINESEARCH METHODS

 $\odot$  in early days, pick  $\alpha_k$  to minimize

$$f(x_k + \alpha p_k)$$

- exact linesearch—univariate minimization
- rather expensive and certainly not cost effective
- o modern methods: inexact linesearch
- $\diamond\,$  ensure steps are neither too long nor too short
- $\diamond\,$ try to pick "useful" initial stepsize for fast convergence
- best methods are either
- ▷ "backtracking- Armijo" or
- ⋄ "Armijo-Goldstein"

based

### STEPS MIGHT BE TOO SHORT

The objective function  $f(x)=x^2$  and the iterates  $x_{k+1}=x_k+\alpha_k p_k$  generated by the descent directions  $p_k=-1$  and steps  $\alpha_k=1/2^{k+1}$  from  $x_0=2$ 

### BACKTRACKING LINESEARCH

Procedure to find the stepsize  $\alpha_k$ :

Given 
$$\alpha_{\text{init}} > 0$$
 (e.g.,  $\alpha_{\text{init}} = 1$ )  
let  $\alpha^{(0)} = \alpha_{\text{init}}$  and  $l = 0$   
Until  $f(x_k + \alpha^{(l)}p_k)$  "<"  $f_k$   
set  $\alpha^{(l+1)} = \tau\alpha^{(l)}$ , where  $\tau \in (0,1)$  (e.g.,  $\tau = \frac{1}{2}$ )  
and increase  $l$  by 1  
Set  $\alpha_k = \alpha^{(l)}$ 

- $\odot~$  this prevents the step from getting too small . . . but does not prevent too large steps relative to decrease in f
- o need to tighten requirement

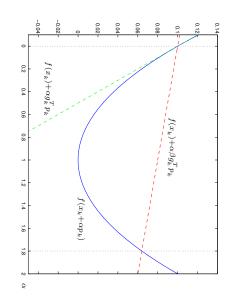

$$f(x_k + \alpha^{(l)}p_k) "<" f_k$$

#### ARMIJO CONDITION

In order to prevent large steps relative to decrease in f, instead require

$$f(x_k + \alpha_k p_k) \le f(x_k) + \alpha_k \beta g_k^T p_k$$

for some 
$$\beta \in (0, 1)$$
 (e.g.,  $\beta = 0.1$  or even  $\beta = 0.0001$ )

## SATISFYING THE ARMIJO CONDITION

**Theorem 2.1.** Suppose that  $f \in C^1$ , that g(x) is Lipschitz continuous with Lipschitz constant  $\gamma(x)$ , that  $\beta \in (0,1)$  and that p is a descent direction at x. Then the Armijo condition

$$f(x + \alpha p) \leq f(x) + \alpha \beta g(x)^T p$$

is satisfied for all  $\alpha \in [0, \alpha_{\max(x)}]$ , where

$$\kappa_{\text{max}} = \frac{2(\beta - 1)g(x)^T p}{\gamma(x) \|p\|_2^2}$$

## **BACKTRACKING-ARMIJO LINESEARCH**

Procedure to find the stepsize  $\alpha_k$ :

Given 
$$\alpha_{\text{init}} > 0$$
 (e.g.,  $\alpha_{\text{init}} = 1$ )  
let  $\alpha^{(0)} = \alpha_{\text{init}}$  and  $l = 0$   
Until  $f(x_k + \alpha^{(l)}p_k) \le f(x_k) + \alpha^{(l)}\beta g_k^T p_k$   
set  $\alpha^{(l+1)} = \tau \alpha^{(l)}$ , where  $\tau \in (0, 1)$  (e.g.,  $\tau = \frac{1}{2}$ )  
and increase  $l$  by 1  
Set  $\alpha_k = \alpha^{(l)}$ 

#### PROOF OF THEOREM 2.1

Taylor's theorem (Theorem 1.1) +

$$\alpha \le \frac{2(\beta - 1)g(x)^T p}{\gamma(x) \|p\|_2^2},$$

$$f(x + \alpha p) \le f(x) + \alpha g(x)^T p + \frac{1}{2} \gamma(x) \alpha^2 \|p\|^2$$

$$\le f(x) + \alpha g(x)^T p + \alpha (\beta - 1) g(x)^T p$$

$$= f(x) + \alpha \beta g(x)^T p$$

 $\downarrow$ 

## THE ARMIJO LINESEARCH TERMINATES

backtracking-Armijo linesearch terminates with  $p_k$  is a descent direction at  $x_k$ . Then the stepsize generated by the tinuous with Lipschitz constant  $\gamma_k$  at  $x_k$ , that  $\beta \in (0,1)$  and that Corollary 2.2. Suppose that  $f \in C^1$ , that g(x) is Lipschitz con-

$$\alpha_k \ge \min\left(\alpha_{\text{init}}, \frac{2\tau(\beta-1)g_k^T p_k}{\gamma_k ||p_k||_2^2}\right)$$

## GENERIC LINESEARCH METHOD

Given an initial guess  $x_0$ , let k=0

Set  $x_{k+1} = x_k + \alpha_k p_k$ , and increase k by 1

Until convergence:

Find a descent direction  $p_k$  at  $x_k$ 

Compute a stepsize  $\alpha_k$  using a

backtracking-Armijo linesearch along  $p_k$ 

## PROOF OF COROLLARY 2.2

Theorem 2.1  $\Longrightarrow$  linesearch will terminate as soon as  $\alpha^{(l)} \le \alpha_{\text{max}}$ .

- 2 cases to consider:
- 1. May be that  $\alpha_{\mathrm{init}}$  satisfies the Armijo condition  $\Longrightarrow \alpha_k = \alpha_{\mathrm{init}}$
- 2. Otherwise, must be a last linesearch iteration (the *l*-th) for which

$$\alpha^{(l)} > \alpha_{\max} \implies \alpha_k \ge \alpha^{(l+1)} = \tau \alpha^{(l)} > \tau \alpha_{\max}$$

Combining these 2 cases gives required result.

## GLOBAL CONVERGENCE THEOREM

tinuous on  $\mathbb{R}^n$ . Then, for the iterates generated by the Generic Linesearch Method, **Theorem 2.3.** Suppose that  $f \in C^1$  and that g is Lipschitz con-

either

$$g_l = 0$$
 for some  $l \ge 0$ 

S.

$$\lim_{k \to \infty} f_k = -\infty$$

Or.

$$\lim_{k\to\infty}\min\left(|p_k^Tg_k|,|p_k^Tg_k|/||p_k||_2\right)=0.$$

### PROOF OF THEOREM 2.3

Suppose that  $g_k \neq 0$  for all k and that  $\lim_{k \to \infty} f_k > -\infty$ . Armijo  $\Longrightarrow$ 

$$f_{k+1} - f_k \le \alpha_k \beta p_k^T g_k$$

for all  $k \Longrightarrow$  summing over first j iterations

$$f_{j+1} - f_0 \le \sum_{k=0}^{j} \alpha_k \beta p_k^T g_k$$

LHS bounded below by assumption  $\Longrightarrow$  RHS bounded below. Sum composed of -ve terms  $\Longrightarrow$ 

$$\lim_{k \to \infty} \alpha_k | p_k^T g_k | = 0$$

Let

$$\mathcal{K}_1 \stackrel{\text{def}}{=} \left\{ k \mid \alpha_{ ext{init}} > \frac{2\tau(\beta - 1)g_k^T p_k}{\gamma \|p_k\|_2^2} \right\} \& \mathcal{K}_2 \stackrel{\text{def}}{=} \{1, 2, \ldots\} \setminus \mathcal{K}_1$$

where  $\gamma$  is the assumed uniform Lipschitz constant.

#### **EXAMPLES**

Steepest-descent direction.  $p_k = -g_k$ 

$$\lim_{k\to\infty} \min\left(|p_k^T g_k|,|p_k^T g_k|/\|p_k\|_2\right) = 0 \implies \lim_{k\to\infty} g_k = 0$$

Newton-like direction:  $p_k = -B_k^{-1}g_k$ 

$$\lim_{k \to \infty} \min \left( |p_k^T g_k|, |p_k^T g_k| / ||p_k||_2 \right) = 0 \implies \lim_{k \to \infty} g_k = 0$$

provided  $B_k$  is uniformly positive definite

Conjugate-gradient direction:  $p_k = \text{any conjugate-gradient}$  approximation to minimizer of  $f_k + p^T g_k + \frac{1}{2} p^T B_k p \approx f(x_k + p)$ 

$$\lim_{k \to \infty} \min \left( |p_k^T g_k|, |p_k^T g_k| / ||p_k||_2 \right) = 0 \implies \lim_{k \to \infty} g_k = 0$$

provided  $B_k$  is uniformly positive definite

For  $k \in \mathcal{K}_1$ ,

$$\alpha_k \ge \frac{2\tau(\beta - 1)g_k^T p_k}{\gamma \|p_k\|_2^2}$$

$$\Rightarrow \alpha_k p_k^T g_k \le \frac{2\tau(\beta - 1)}{\gamma} \left(\frac{g_k^T p_k}{\|p_k\|}\right)^2 < 0$$

$$\Rightarrow \lim_{k \in \mathcal{K}_1 \to \infty} \frac{|p_k^T g_k|}{\|p_k\|_2} = 0.$$

1

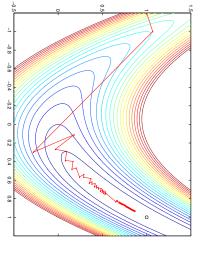

For  $k \in \mathcal{K}_2$ ,

$$lpha_k \geq lpha_{ ext{init}}$$
  $\lim_{k \in \mathcal{K}_2 o \infty} |p_k^T g_k| = 0.$ 

2

Combining (1) and (2) gives the required result.

## STEEPEST DESCENT EXAMPLE

Contours for the objective function  $f(x,y) = 10(y-x^2)^2 + (x-1)^2$ , and the iterates generated by the Generic Linesearch steepest-descent method

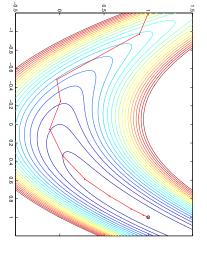

## METHOD OF STEEPEST DESCENT (cont.)

- $\odot$  archetypical globally convergent method
- $\circ$  many other methods resort to steepest descent in bad cases
- o not scale invariant
- $\odot$  convergence is usually very (very!) slow (linear)
- $\odot\,$  numerically often not convergent at all

# MORE GENERAL DESCENT METHODS (cont.)

- $\odot$  may be viewed as "scaled" steepest descent
- $\odot$  convergence is often faster than steepest descent
- $\odot$  can be made scale invariant for suitable  $B_k$

### NEWTON METHOD EXAMPLE

Contours for the objective function  $f(x,y)=10(y-x^2)^2+(x-1)^2$ , and the iterates generated by the Generic Linesearch Newton method
