Optimality Conditions: What We Know So Far

First Order Optimality Conditions for Constrained Nonlinear Programming

Lecture 9, Continuous Optimisation Oxford University Computing Laboratory, HT 2006 Notes by Dr Raphael Hauser (hauser@comlab.ox.ac.uk)

- Necessary optimality conditions for unconstrained optmization: $\nabla f(x) = 0$ and $D^2 f(x) \succeq 0$.
- Sufficient optimality conditions: $\nabla f(x) = 0$, $D^2 f(x) > 0$.
- Sufficiency occurs because $D^2 f(x) \succ 0$ guarantees that f is locally strictly convex.
- Indeed, if convexity of f is a given, ∇f(x*) = 0 is a necessary and sufficient condition.

• In the exercises, we used the fundamental theorem of linear inequalities to derive the LP duality theorem. This yielded the necessary and sufficient optimality conditions

$$A^{\mathsf{T}}y = c, \quad y \ge 0$$
$$Ax \le b$$
$$c^{\mathsf{T}}x - b^{\mathsf{T}}y = 0$$

for the LP problem

(P)
$$\max_{x \in \mathbb{R}^n} c^{\mathsf{T}} x$$
s.t. $Ax \le b$.

• Writing (P) in the form

$$\min f(x)$$

s.t. $g_i(x) \ge 0$ $(i = 1, \dots, m),$

the optimality conditions can be rewritten as

$$\nabla f(x) - \sum_{i=1}^{m} y_i \nabla g_i(x) = 0$$

$$g_i(x) \ge 0 \quad (i = 1, ..., m)$$

$$y^{\mathsf{T}} (Ax - b) = 0, \text{ that is,} [g_1(x) \dots g_m(x)] y = 0.$$

- We will see that the last condition could have been strengthened to $y_ig_i(x) = 0$ for all *i*.
- LP is the simplest example of a constrained convex optimisation problem: minimise a convex function over a convex domain. Again convexity implies that first order conditions are enough.

More generally, let

$$\begin{array}{ll} (\mathsf{NLP}) & \min_{x \in \mathbb{R}^n} f(x) \\ & \mathsf{s.t.} & g_i(x) = 0, \quad (i \in \mathcal{E}), \\ & g_j(x) \geq 0 \quad (j \in \mathcal{I}). \end{array}$$

The following will emerge under appropriate regularity assumptions:

- i) Convex problems have first order necessary and sufficient optimality conditions.
- ii) In general problems, second order conditions introduce local convexity.

I. First Order Necessary Optimality Conditions

Definition 1 Let $x^* \in \mathbb{R}^n$ be feasible for the problem (NLP). We say that the inequality constraint $g_j(x) \ge 0$ is *active* at x^* if $g(x^*) = 0$. We write $\mathcal{A}(x^*) := \{j \in \mathcal{I} : g_j(x^*) = 0\}$ for the set of indices corresponding to active inequality constraints.

Of course, equality constraints are always active, but we will account for their indices separately.

If $\mathcal{J} \subset \mathcal{E} \cup \mathcal{I}$ is a subset of indices, we will write

- $g_{\mathcal{J}}$ for the vector-valued map that has g_i $(i \in \mathcal{J})$ as components in some specific order,
- g for $g_{\mathcal{E}\cup\mathcal{I}}$.

Definition 2: If $\{\nabla g_i : i \in \mathcal{E} \cup \mathcal{A}(x^*)\}$ is a linearly independent set of vectors, we say that the *linear independence constraint qualification* (LICQ) holds at x^* .

Lemma 1: Let x^* be a feasible point of (NLP) where the LICQ holds and let $d \in \mathbb{R}^n$ be a vector such that

$$d \neq 0,$$

$$d^{\mathsf{T}} \nabla g_i(x^*) = 0, \qquad (i \in \mathcal{E}),$$

$$d^{\mathsf{T}} \nabla g_j(x^*) \ge 0, \qquad (j \in \mathcal{A}(x^*)).$$

(1)

Then for $\epsilon > 0$ small enough there exists a path $x \in C^k ((-\epsilon, +\epsilon), \mathbb{R}^n)$ such that

$$\begin{aligned} x(0) &= x^*, \\ \frac{d}{dt}x(0) &= d, \\ g_i(x(t)) &= td^{\mathsf{T}} \nabla g_i(x^*) \quad (i \in \mathcal{E} \cup \mathcal{A}(x^*), t \in (-\epsilon, \epsilon)), \end{aligned}$$
(2)

so that

$$g_i(x(t)) = 0 \quad (i \in \mathcal{E}, t \in (-\epsilon, \epsilon)),$$

$$g_j(x(t)) \ge 0 \quad (j \in \mathcal{I}, t \ge 0).$$

- Proof:
- Let $l = |\mathcal{A}(x^*) \cup \mathcal{E}|$. Since the LICQ holds, it is possible to choose $Z \in \mathbb{R}^{(n-l) \times n}$ such that $\begin{bmatrix} Dg_{\mathcal{A}(x^*) \cup \mathcal{E}}(x^*) \\ Z \end{bmatrix}$ is a nonsingular $n \times n$ matrix.
- Let $h: \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ be defined by

$$(x,t) \mapsto \begin{bmatrix} g_{\mathcal{A}(x^*)\cup\mathcal{E}}(x) - tDg_{\mathcal{A}(x^*)\cup\mathcal{E}}(x^*)d \\ Z(x-x^*-td) \end{bmatrix}$$

• Then $Dh(x^*, 0) = [D_x h(x^*, 0) D_t h(x^*, 0)]$, where

$$D_x h(x^*, 0) = \begin{bmatrix} Dg_{\mathcal{A}(x^*) \cup \mathcal{E}}(x^*) \\ Z \end{bmatrix} \text{ and }$$
$$D_t h(x^*, 0) = -\begin{bmatrix} Dg_{\mathcal{A}(x^*) \cup \mathcal{E}}(x^*)d \\ Zd \end{bmatrix} = -D_x h(x^*, 0)d$$

• Since $D_x h(x^*, 0)$ is nonsingular, the Implicit Function Theorem implies that for $\tilde{\epsilon} > 0$ small enough there exists a unique C^k function $x : (-\tilde{\epsilon}, \tilde{\epsilon}) \to \mathbb{R}^n$ and a neighbourhood $\mathfrak{V}(x^*)$ such that for $x \in \mathfrak{V}(x^*)$, $t \in (-\tilde{\epsilon}, \tilde{\epsilon})$,

$$h(x,t) = 0 \Leftrightarrow x = x(t).$$

• In particular, we have $x(0) = x^*$ and $g_i(x(t)) = td^{\top} \nabla g(x^*)$ for all $i \in \mathcal{A}(x^*) \cup \mathcal{E}$ and $t \in (-\tilde{\epsilon}, \tilde{\epsilon})$. (1) therefore implies that $g_i(x(t)) = 0$ $(i \in \mathcal{E})$ and $g_i(x(t)) \ge 0$ $(i \in \mathcal{A}(x^*), t \in [0, \tilde{\epsilon}))$.

- On the other hand, since $g_i(x^*) > 0$ $(i \notin \mathcal{A}(x^*))$, the continuity of x(t) implies that there exists $\epsilon \in (0, \tilde{\epsilon})$ such that $g_j(x(t)) > 0$ $(j \in \mathcal{I} \setminus \mathcal{A}(x^*), t \in (-\epsilon, \epsilon))$.
- Finally,

$$\frac{d}{dt}x(0) = -(D_x h(x^*, 0))^{-1} D_t h(x^*, 0) = d$$

follows from the second part of the Implicit Function Theorem. $\hfill \square$

- Since d satisfies (1), Lemma 1 implies that there exists a path $x : (-\epsilon, \epsilon) \to \mathbb{R}^n$ that satisfies (2).
- Taylor's theorem then implies that

$$f(x(t)) = f(x^*) + td\nabla f(x^*) + O(t^2) < f(x^*)$$

for $0 < t \ll 1$.

• Since (2) shows that x(t) is feasible for $t \in [0, \epsilon)$, this contradicts the assumption that x^* is a local minimiser.

Theorem 1: If x^* is a local minimiser of (NLP) where the LICQ holds then

$$abla f(x^*) \in \operatorname{cone}\left(\{\pm \nabla g_i(x^*): i \in \mathcal{E}\} \cup \{\nabla g_j(x^*): j \in \mathcal{A}(x^*)\}\right).$$

Proof:

• Suppose our claim is wrong. Then the fundamental theorem of linear inequalities implies that there exists a vector $d\in\mathbb{R}^n$ such that

$$d^{\mathsf{T}} \nabla g_j(x^*) \ge 0, \qquad (j \in \mathcal{A}(x^*)),$$

$$\pm d^{\mathsf{T}} \nabla g_i(x^*) \ge 0, \quad (\text{i.e., } d^{\mathsf{T}} \nabla g_i(x^*) = 0) \qquad (i \in \mathcal{E}),$$

$$d^{\mathsf{T}} \nabla f(x^*) < 0.$$

Comments:

• The condition

 $abla f(x^*) \in \operatorname{cone}\left(\{\pm \nabla g_i(x^*): i \in \mathcal{E}\} \cup \{\nabla g_j(x^*): j \in \mathcal{A}(x^*)\}\right)$

is equivalent to the existence of $\lambda \in \mathbb{R}^{|\mathcal{E} \cup \mathcal{I}|}$ such that

$$\nabla f(x^*) = \sum_{i \in \mathcal{E} \cup \mathcal{I}} \lambda_i \nabla g_i(x^*), \tag{3}$$

where $\lambda_j \geq 0$ $(j \in \mathcal{A}(x^*))$ and $\lambda_j = 0$ for $(j \in \mathcal{I} \setminus \mathcal{A}(x^*))$.

• x^* was assumed feasible, that is, $g_i(x^*) = 0$ for all $i \in \mathcal{E}$ and $g_j(x^*) \ge 0$ for all $j \in \mathcal{I}$.

Thus, Theorem 1 shows that when x^* is a local minimiser where the LICQ holds, then the following so-called Karush-Kuhn-Tucker (KKT) conditions must hold:

Corollary 1: There exist Lagrange multipliers $\lambda \in \mathbb{R}^{|\mathcal{I} \cup \mathcal{E}|}$ such that

$$abla f(x) - \sum_{i \in \mathcal{I} \cup \mathcal{E}} \lambda_i
abla g_i(x) = 0$$
 $g_i(x) = 0$ $(i \in \mathcal{E})$
 $g_j(x) \ge 0$ $(j \in \mathcal{I})$
 $\lambda_j g_j(x) = 0$ $(j \in \mathcal{I})$
 $\lambda_j \ge 0$ $(j \in \mathcal{I}).$

We can formulate this result in slightly more abstract form in terms of the Lagrangian associated with (NLP):

$$: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$$
$$(x, \lambda) \mapsto f(x) - \sum_{i=1}^m \lambda_i g_i(x).$$

The balance equation

 \mathcal{L}

$$\nabla f(x) - \sum_{i \in \mathcal{I} \cup \mathcal{E}} \lambda_i \nabla g_i(x) = 0$$

says that the derivative of the Lagrangian with respect to the x coordinates is zero.

Putting all the pieces together, we obtain the following result:

Corollary 2: First Order Necessary Optimality Conditions.

If x^* is a local minimiser of (NLP) where the LICQ holds then there exists $\lambda^* \in \mathbb{R}^m$ such that (x^*, λ^*) solves the following system of inequalities,

$$egin{aligned} D_x\mathcal{L}(x^*,\lambda^*) &= 0, \ \lambda_j^* &\geq 0 \quad (j\in\mathcal{I}), \ \lambda_i^*g_i(x^*) &= 0 \quad (i\in\mathcal{E}\cup\mathcal{I}), \ g_j(x^*) &\geq 0 \quad (j\in\mathcal{I}), \ g_i(x^*) &= 0 \quad (i\in\mathcal{E}). \end{aligned}$$

Mechanistic Motivation of KKT Conditions:

A useful picture in unconstrained optimisation is to imagine a point mass m or an infinitesimally small ball that moves on a hard surface

$$F := \left\{ (x, f(x)) : x \in \mathbb{R}^n \right\}$$

without friction.

• The external forces acting on the point mass are the gravity force $m\vec{g} = \begin{pmatrix} 0\\ -mg \end{pmatrix}$ and the reaction force

$$\vec{N}_f = \frac{mg}{1 + \|\nabla f(x)\|^2} \begin{pmatrix} -\nabla f(x) \\ 1 \end{pmatrix}.$$

• The total external force

$$\vec{R} = m\vec{g} + \vec{N}_f = \frac{mg}{1 + \|\nabla f(x)\|^2} \begin{bmatrix} -\nabla f(x) \\ -\|\nabla f(x)\|^2 \end{bmatrix} \perp \vec{N}_f$$

equals zero if and only if $\nabla f(x) = 0$ (i.e., a stationary point).

Extension to constrained optimisation:

We can interpret an inequality constraint $g(x) \ge 0$ as a hard smooth surface

$$G := \left\{ (x, z) \in \mathbb{R}^n \times \mathbb{R} : g(x) = 0 \right\}$$

that is parallel to the *z*-axis everywhere and keeps the point mass from rolling into the domain where g(x) < 0.

Such a surface can exert only a normal force that points towards the domain $\{x : g_j(x) > 0\}$.

Therefore, the reaction force must be of the form $\vec{N}_g = \mu_g \begin{pmatrix} \nabla g(x) \\ 0 \end{pmatrix}$, where $\mu_g \ge 0$.

- When the test mass is slightly moved from a local maximiser, then the external forces will pull it further away.
- In a neighbourhood of a local minimiser they will restore the point mass to its former position.
- This is expressed by the second order optimality conditions: an equilibrium position is *stable* if $D^2 f(x) \succ 0$ and instable if $D^2 f(x) \prec 0$.

• In the picture the point mass is at rest and does not roll to lower terrain if the sum of external forces is zero, that is, $\vec{N_f} + \vec{N_g} + m\vec{g} = 0.$

• Since
$$\vec{N}_f = \mu_f \begin{pmatrix} -\nabla f(x) \\ 1 \end{pmatrix}$$
 for some $\mu_f \ge 0$, we find
$$\mu_f \begin{bmatrix} -\nabla f(x) \\ 1 \end{bmatrix} + \mu_g \begin{bmatrix} \nabla g(x) \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ -mg \end{bmatrix} = 0,$$

from where it follows that $\mu_f = mg$ and

$$\nabla f(x) = \lambda \nabla g(x) \tag{4}$$

with $\lambda = \mu/mg \ge 0$.

• When multiple inequality constraints are present, the the balance equation (4) must thus be replaced with

$$abla f(x) = \sum_{j \in \mathcal{I}} \lambda_j \nabla g_j(x)$$

for some $\lambda_j \geq 0$.

• Since constraints for which $g_j(x) > 0$ cannot excert a force on the test mass, we must set $\lambda_j > 0$ for these indices, or equivalently, the equation $\lambda_j g_j(x) = 0$ must hold for all $j \in \mathcal{I}$.

What about equality constraints?

Replacing $g_i(x) = 0$ by the two inequality constraints $g_i(x) \ge 0$ and $-g_i(x) \ge 0$, our mechanistic interpretation yields two parallel surfaces G_i^+ and G_i^- , leaving an infinitesimally thin space between them within which our point mass is constrained to move.

The net reaction force of the two surfaces is of the form

$$\lambda_i^+ \nabla g_i(x) + \lambda_i^- \nabla (-g_i)(x) = \lambda_i \nabla g_i(x),$$

where we replaced the difference $\lambda_i^+ - \lambda_i^-$ of the bound-constrained variables $\lambda_i^+, \lambda_i^- \ge 0$ by a single unconstrained variable $\lambda_i = \lambda_i^+ - \lambda_i^-$.

Note that in this case the conditions $\lambda_i^+ g_i(x) = 0$, $\lambda_i^-(-g_i(x)) = 0$ are satisfied automatically, since $g_i(x) = 0$ if x is feasible.

There are situations in which our mechanical picture is flawed: if two inequality constraints have first order contact at a local minimiser then they cannot annul the horizontal part of \vec{N}_f .

When there are more constraints constraints, then generalisations of this situation can occur. In order to prove the KKT conditions, we must therefore make a regularity assumption like the LICQ.
